Abstract

A new species of the genus Trichosanthes (Cucurbitaceae), T. napoensis, is described and illustrated from Guangxi Province, western China. It is closely related to T. pedata Merr. & Chun, but it can be distinguished from the latter by having 3-fid tendrils, a fruit apex with a prominent protrusion, and oblong-elliptical seeds with a ridge at the margin.

Keywords: China, Cucurbitaceae, new species, Trichosanthes

Introduction

The genus Trichosanthes L. (1753:1008) is one of the largest genera of family Cucurbitaceae, consists of 90–100 species and is distributed from India through China to Japan and Australia and Fiji (Huang & Jeffrey 2011; Cooper & de Boer 2011; de Boer & Thulin 2012; Yueh & Cheng 1974, 1980). Most species have large white or pale yellow petals with conspicuously fringed margins, with the fringes sometimes several cm long. Recent results of molecular systematics and biogeography have indicated that Trichosanthes was not monophyletic, and as a result the fringeless genus Gymnopetalum Arn. (1840:52) was merged with it to retain monophyly (de Boer et al. 2012). A prior study showed that a single species of Trichosanthes described from the Caribbean did not belong in the genus, and this was transferred to a new genus, Linnaeosicyos H. Schaef. & Kocyan (Schafer et al. 2008).

There are approximately 40 species of Trichosanthes in China (14 endemic), most of which have fruit that are globose, ovoid, or fusiform, fleshy, berries usually glabrous, with seeds suspended in pulp (Huang et al. 2009; Huang & Jeffrey 2011; Yueh & Cheng 1974, 1980). Morphologically, Trichosanthes is characterized by the morphology of leaves and flowers and the size and form of bracts, and the morphology of fruits and seeds can be especially helpful to identify the different species (Huang & Jeffrey 2011; de Boer & Thulin 2012; Yueh & Cheng 1974, 1980).

During our field work in the Fourth National Survey on Chinese Material Medical Resources, unusual endemic species of Trichosanthes was collected in Napo County, Guangxi Province. Based on comparisons with relevant specimens in IBK, GNU, GXMG, NAS and PE, we concluded that these specimens represent a new species as described below.

Taxonomy

Trichosanthes napoensis D. X. Nong & L. Q. Huang, sp. nov. (Figs. 1–2)
Type:—CHINA. Guangxi Zhuangzu Autonomous Region, Baise City, Napo County, Pingmeng Town, Nianjing Village, Xima Tun, Roadside and shrub of Limestone foothills, alt. 978 m, 12 October 2014, D. X. Nong 451026141012021LY (Holotype: GXMG! (specimen with fruit); isotypes: GXMG!, CMMI!).
Lianas, woody. Stems robust, striate, glabrous, lenticels densely covered. Tendrils usually 3-fid. Leaves pedately 5-foliolate, thinly leathery; adaxially deep green, abaxially pale green, leaf blade rough, white punctuate dense on both surface, remotely sinuate-dentate; petiole 7–9 cm, glabrous; central leaflets oblong-ovate, base nearly truncate, 7–10 × 3.5–4 cm, petiolules 0.5–0.8 cm; lateral leaflets broadly sickled, 4–5 × 2.5–3 cm, base nearly sunken, petiolules of lateral leaflets combined 0.8–1 cm, lateral truncated; secondary veins raised, veins 3–5 pairs. Fruiting peduncle robust, ca. 1.5 cm; fruit red, globose, 6–7 cm in diameter, glabrous, with a protrusion at apex, ca. 0.2 cm. Seeds numerous, yellow-brown, compressed, oblong-elliptic, with ridge at margin, 1.4–1.6 × 0.7–0.9 cm, base nearly sunken, apex truncated and quadrilateral. Flowering not observed, fruiting September–December.

**Distribution & Habitat:** — *Trichosanthes napoensis* is endemic to Napo County, Guangxi, China. It grows on roadside and in thickets on limestone foothills, at elevations of 900–1000 m.

**Etymology:** — The specific epithet ‘napoensis’ refers to the locality where the new species occurs, the Napo County, Baise City, Guangxi Province.

**Paratypes:** — The same locality roadside, 12 October 2014, D. X. Nong & L. Q. Huang 451026141012024LY (paratype, CMMI!).

**Relationships:** — *Trichosanthes napoensis* belongs to *Trichosanthes* sect. *Involucraria* Wight (1840:52 ) and is close to *T. pedata* Merr. & Chun (1934:20 ) in having pedately 5-foliolate leaves and globose fruit but differs by its 3-fid tendrils on the stem, oblong-ovate central leaflet and nearly jointed base lateral leaflets. In addition, *T. napoensis* is characterized by its robust stem, fruit with a prominent protrusion at the apex, seed oblong-elliptic, ridge at the margin, base nearly sunken, truncated and quadrilateral apex (Table1).
